

External and Internal Individual Monitoring of Occupationally Exposed Workers at CNAAA 1 and CNAAA 2 Nuclear Power Plants.

Claudia L. P. Mauricio, Bernardo M. Dantas and
John Hunt

External Dosimetry

Individual monitoring
for photons and neutrons.

External Individual Monitoring of CNAAA Nuclear Power Plants

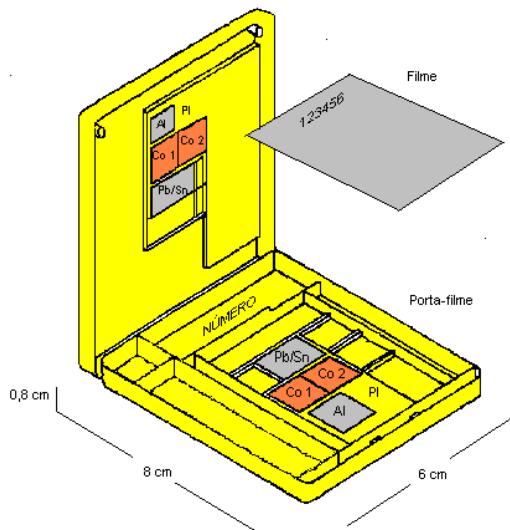

IRD carried out the routine external individual monitoring of all the occupationally exposed workers of the CNAAA NPPs from 1983 to 2008:

- CNAAA 1 started commercial operation in 1985.
- CNAAA 2 started commercial operation in 2000.

IRD external individual monitoring systems:

- whole body photons, with film badge dosimeter;
- extremities photons, with TLD ring and
- whole body neutrons, with TLD albedo dosimeter.

IRD Monitors

IRD thorax film badge individual monitor

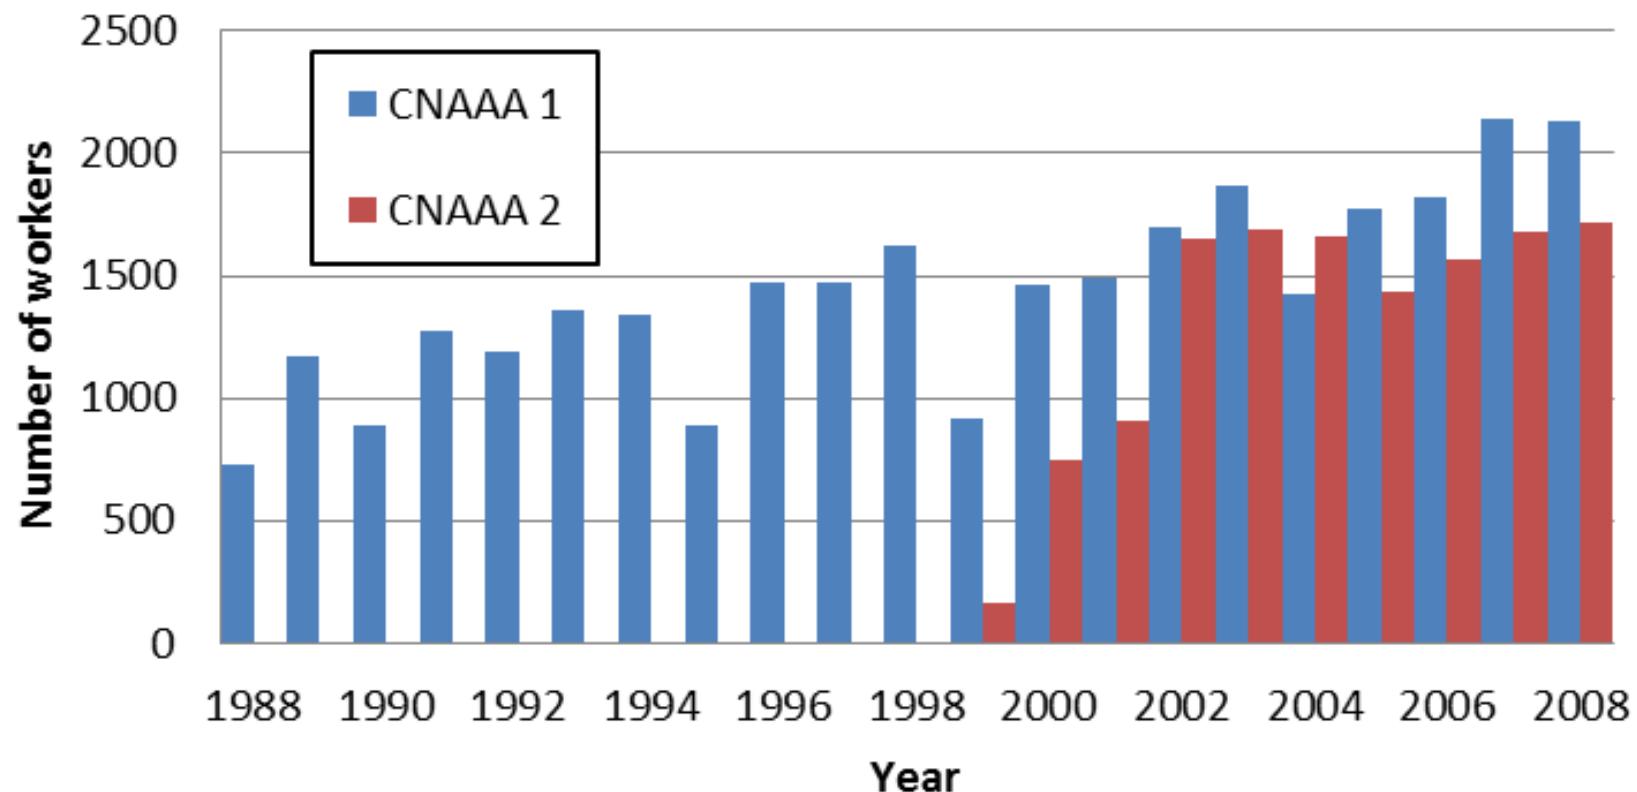

IRD TLD extremity individual monitor (ring)

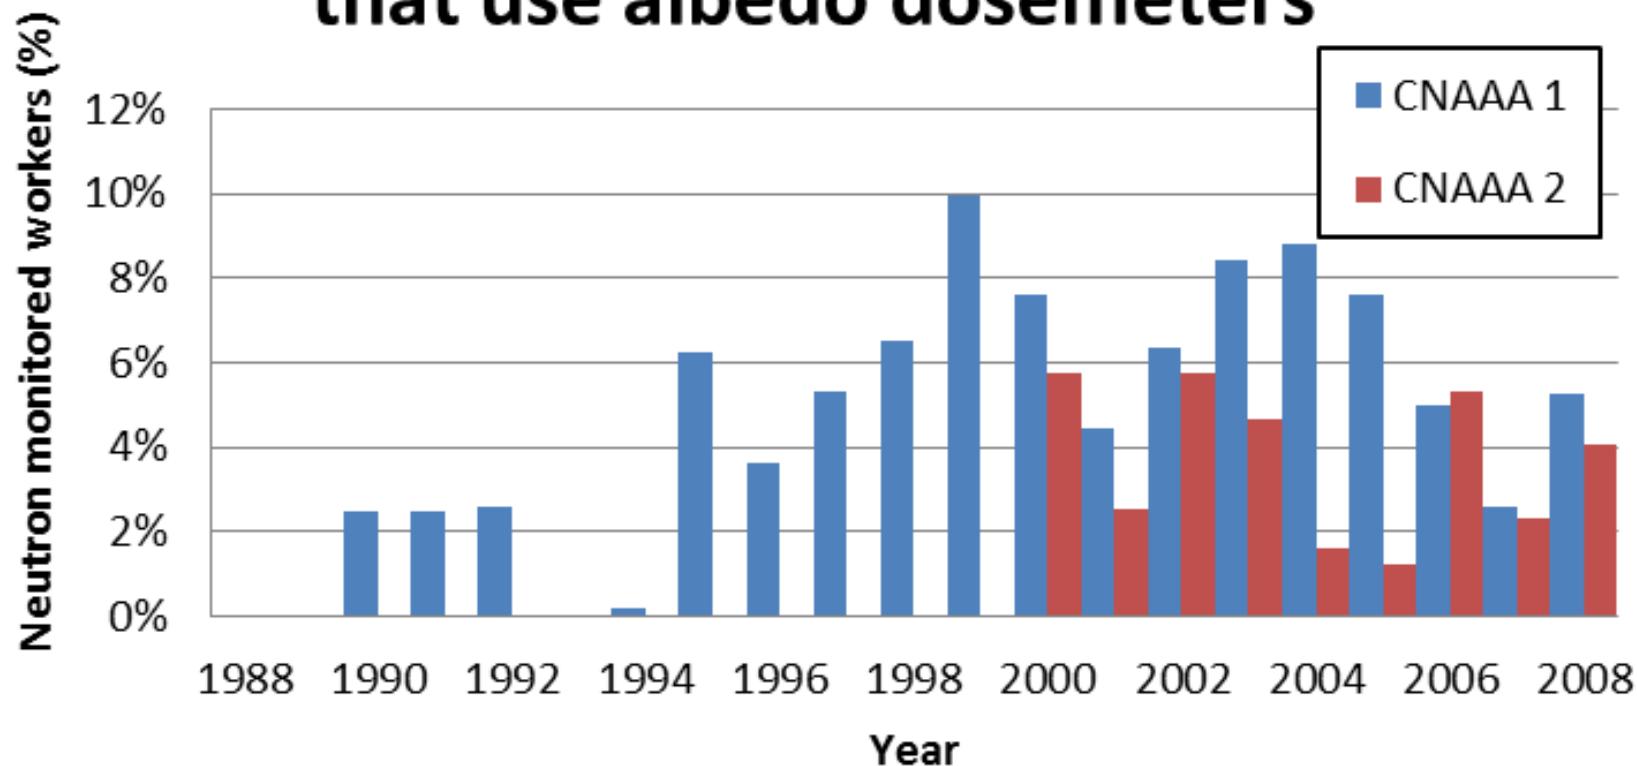

IRD TLD albedo neutron individual monitor

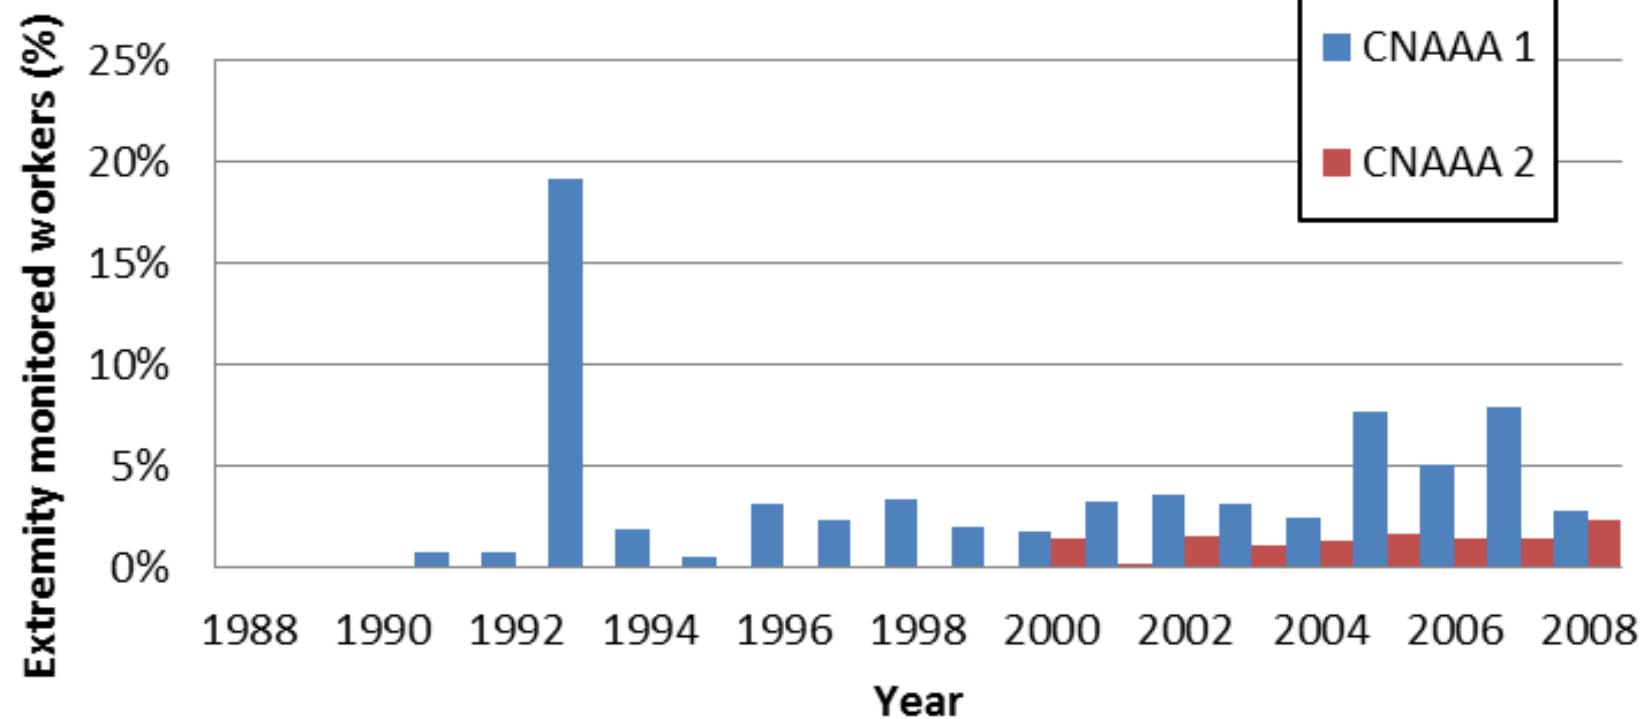

Number of Monitored Workers

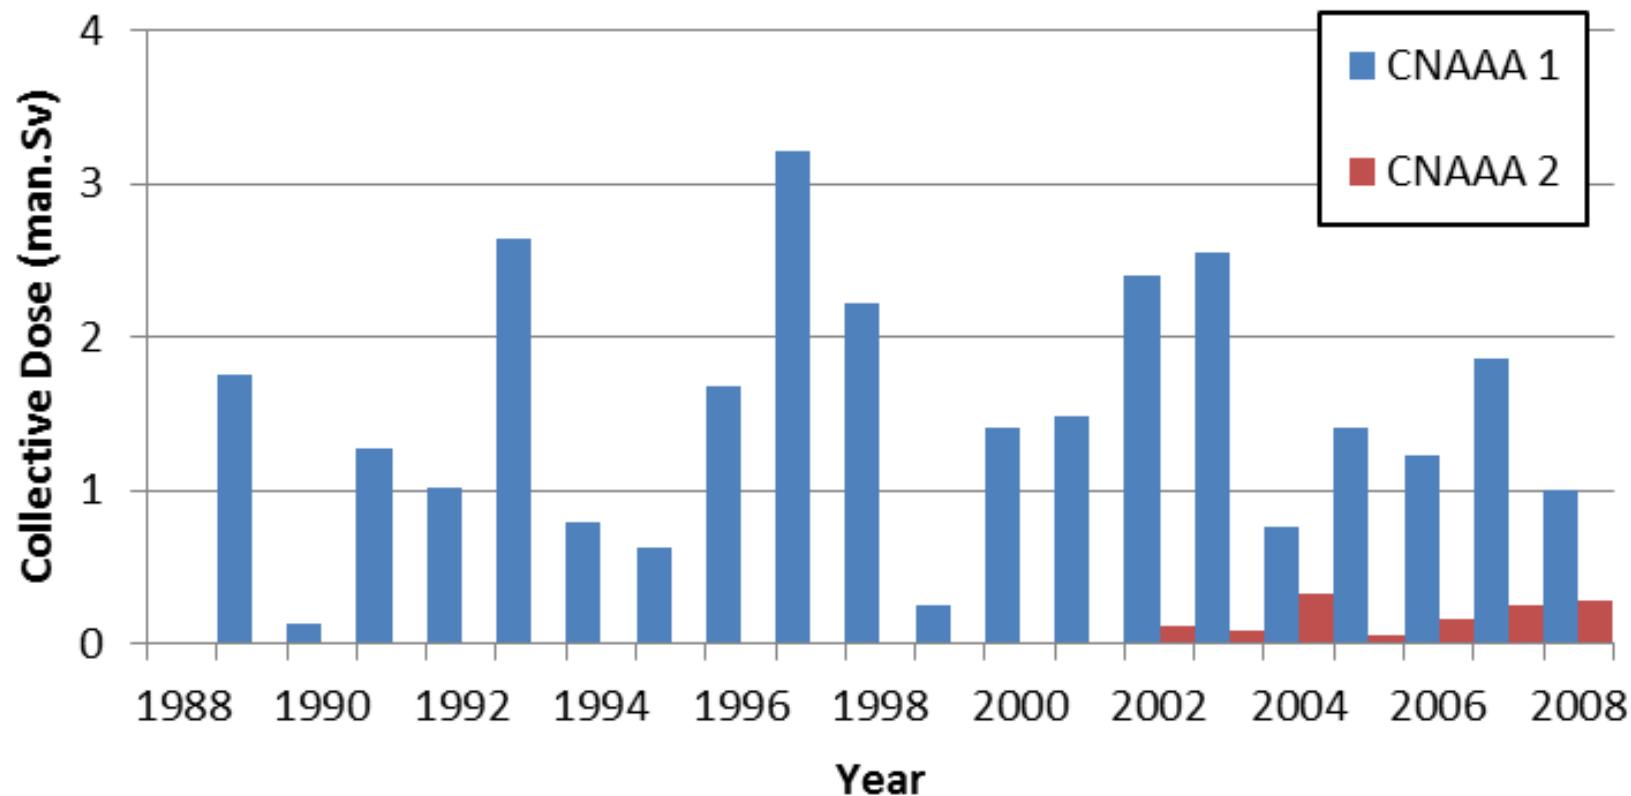

Percentage of monitored workers that use albedo dosimeters

Percentage of monitored workers that use ring dosimeters

Collective Dose

Effective Dose

All the annual effective doses are lower than the occupational limit of 50 mSv in one year (100 mSv in 5 years) and only one is higher than 20 mSv in one year.

➤ CNAAA 1:

- Only 2 doses > 20 mSv:
 - 2003 (27.6 mSv)
 - 1989 (23.5 mSv)
- Most doses \leq 1.0 mSv (75%)

➤ CNAAA 2:

- All doses < 20 mSv
 - Highest dose in 2004 (5.3 mSv)
- Most doses \leq 1.0 mSv (97%)

Neutron Doses

The neutron dose contribution is negligible compared to the photon doses:

➤ CNAAA 1:

- Neutron contribution to annual collective dose < 1%, except in:
 - 1995 (1.1%)
 - 1999 (6.5%)
 - 2003 (1.3%)
- Mean annual neutron effective dose \leq 0.2 mSv.

➤ CNAAA 2:

- Only 1 neutron dose \neq 0.0 mSv:
 - 2003 (0.2 mSv)

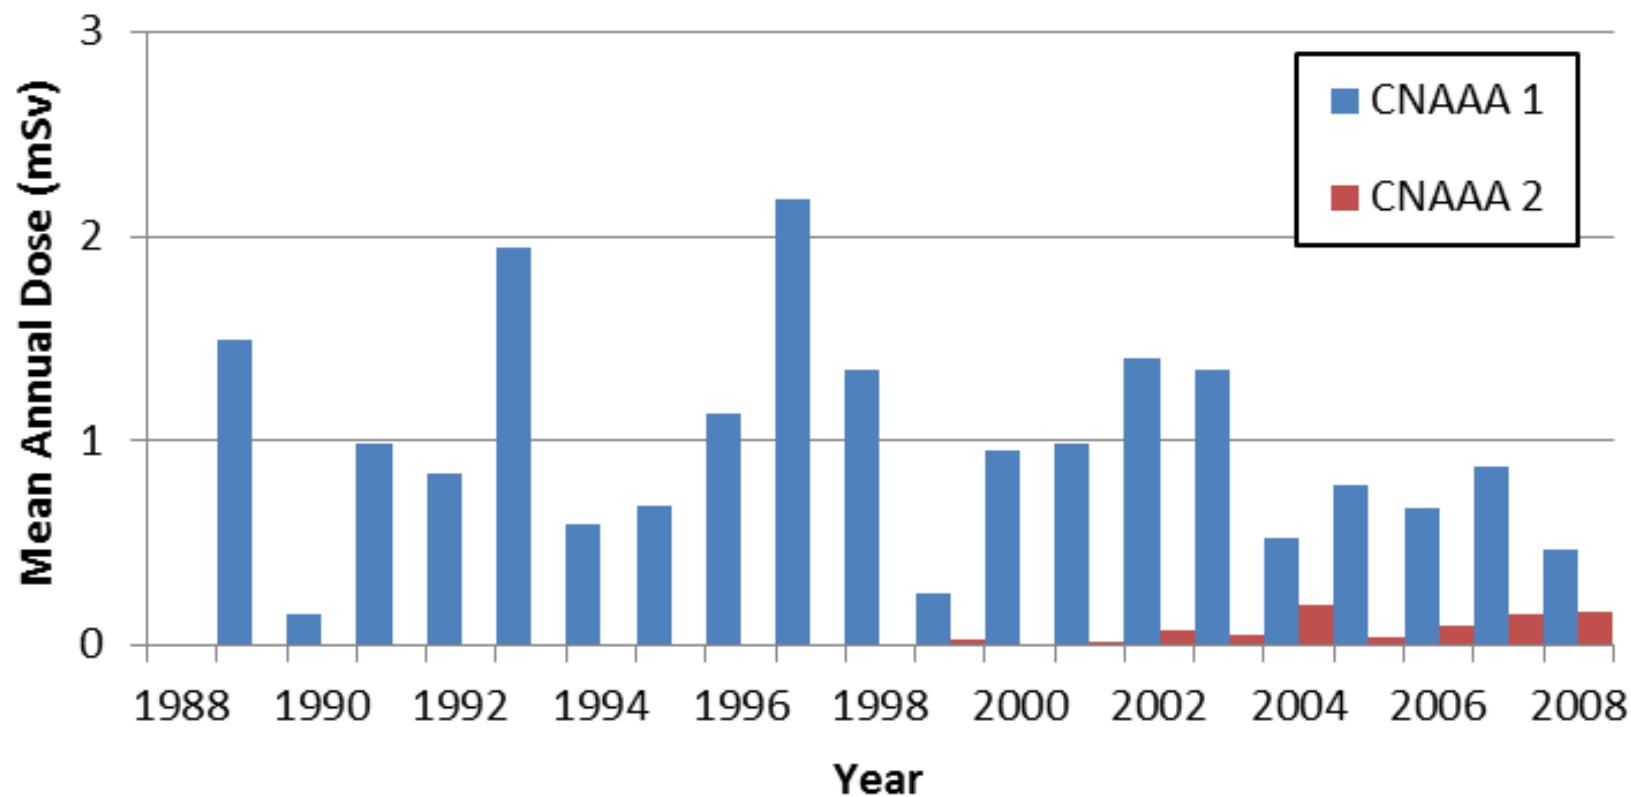

Extremity doses

The annual extremity equivalent doses are very low:

- CNAAA 1:
 - Only 1 dose near the occupational limit (500 mSv)
 - 1993 (390.0 mSv)
 - All others < 25 mSv

- CNAAA 2:
 - All doses < 20 mSv
 - Highest dose in 2003 (17.8 mSv)

Mean Effective Dose per Year

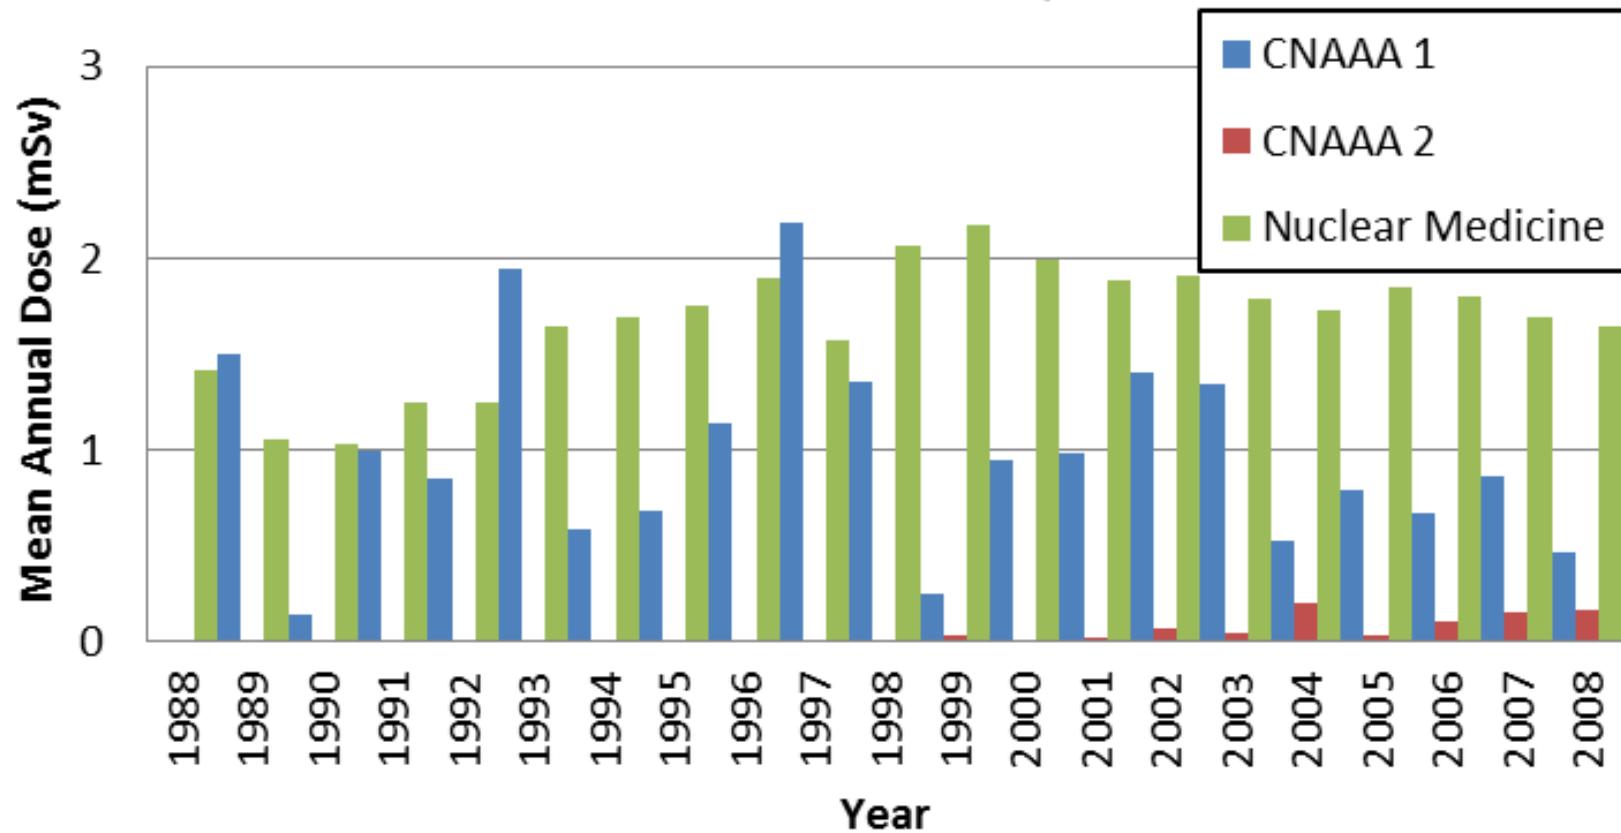

Annual Effective Doses

CNAAA x Nuclear Medicine

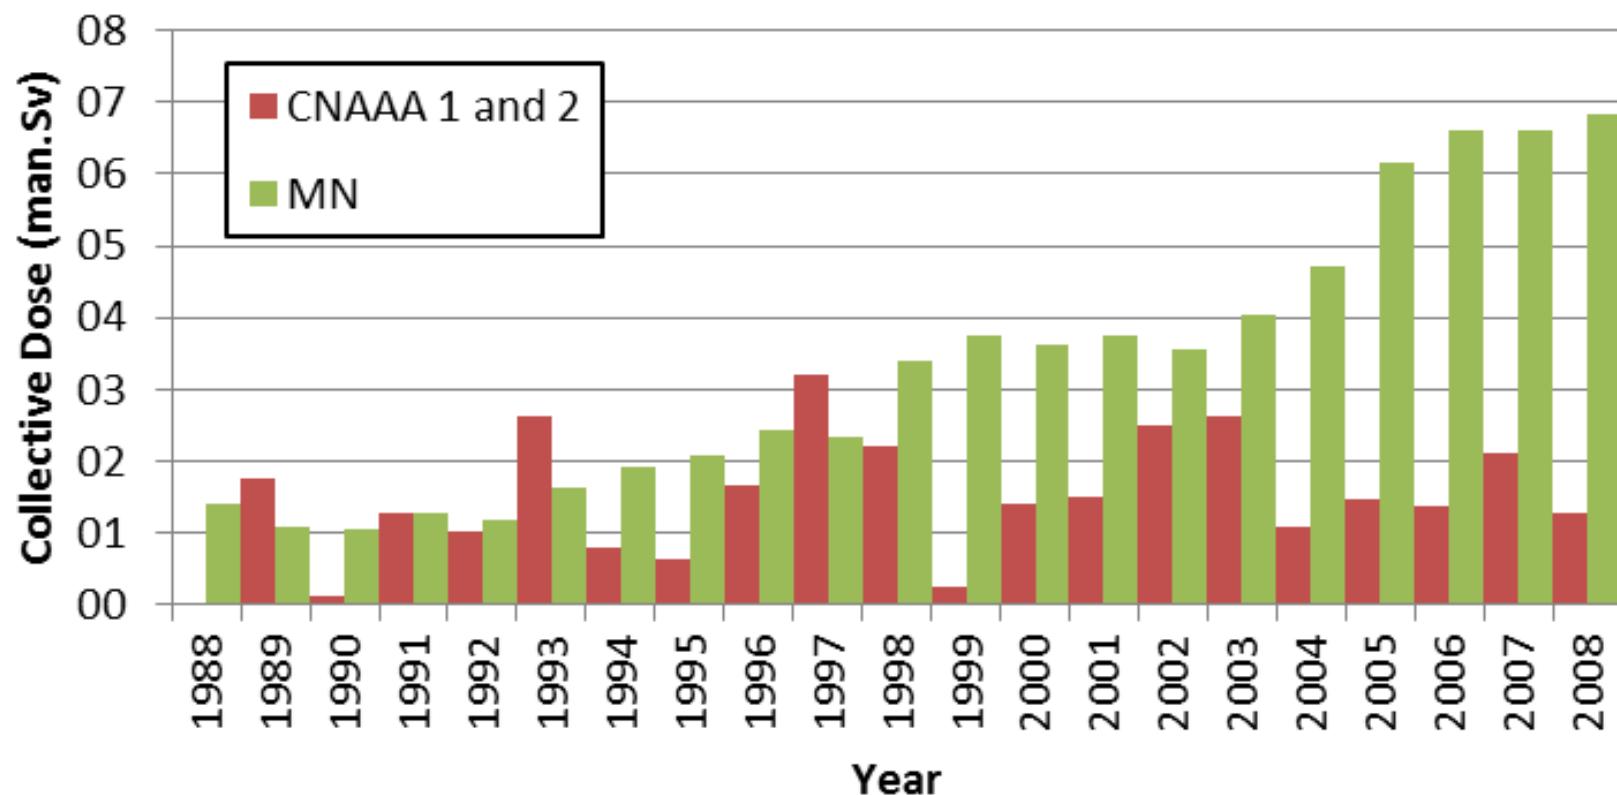

Comparison of occupational doses received at CNAAA 1 and 2 with those received in nuclear medicine services of the state of Rio de Janeiro.

Year	Maximum and Mean Annual Effective Dose (mSv)					
	Doctor	Technician	Nurse	Physicist	CNAAA 1	CNAAA 2
2005	9.0 (0.8)	17.8 (2.9)	21.2 (2.7)	0.7 (0.1)	10.2 (0.8)	3.2 (0.04)
2006	7.4 (0.6)	59.7 (3.3)	23.9 (2.1)	1.4 (0.4)	10.2 (0.7)	3.3 (0.1)
2007	5.2 (0.5)	18.1 (2.9)	10.9 (1.8)	0.8 (0.1)	13.6 (0.9)	5.0 (0.1)
2008	12.9 (0.6)	17.7 (2.6)	14.0 (1.8)	1.8 (0.1)	7.1 (0.5)	4.3 (0.2)

Mean Effective Dose per Year

Collective Dose - Brazil

Internal Dosimetry

In vivo and in vitro measurements

In Vivo and In Vitro Measurements

The in Vivo system is mounted in a van with internal dimensions of 3.30 m x 1.60 m x 1.70 m.

The detection system is able to identify and quantify photon emitters in the energy range of 100 - 3000 keV in the whole body, organs or tissues and urine.

In Vivo and In Vitro Measurements

The NaI(Tl) 8x4 detector used for whole body measurements is calibrated with a plastic-bottle phantom containing standard solutions uniformly distributed among its various sections representing the members of a human body.

The calibration of the NaI(Tl)3x3 thyroid monitor is performed with a neck and thyroid phantom developed at the IRD.

Project TC-IAEA BRA9055

An Internal Dosimetry Network in Brazil

The project IAEA BRA 9055 has resulted in a long term collaboration between the Brazilian internal dosimetry laboratories in Brazil.

The IRD and Eletronuclear internal dosimetry centers have, as a result of the IAEA project, promoted the harmonization of bioassay techniques and dose estimation in case of an emergency response.

In Vivo and In Vitro Measurements

Up to the present moment, 416 internal monitoring measurements were performed on CNEN and ABACC inspectors. The results are all lower than the minimum detectable activity.

It is possible to conclude that the inspection activities at the CNAAA plants is carried out with a high degree of radiation safety.

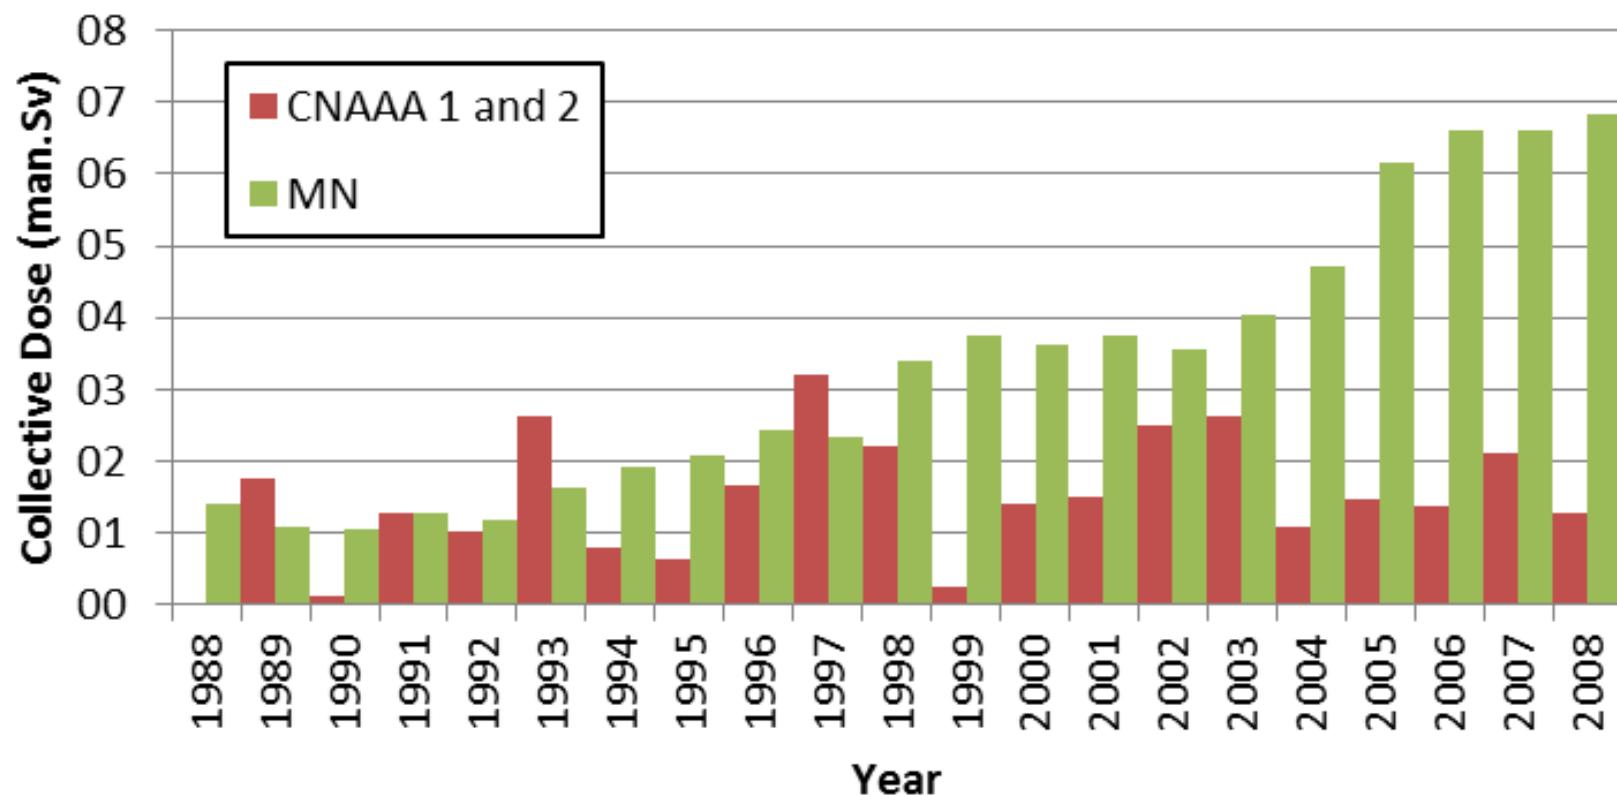

Conclusions

The individual monitoring results of CNAAA 1 and 2 show good ALARA radiation protection practices. The yearly average and collective doses for CNAAA 2 are considerably lower than those of CNAAA 1.

In terms of occupational radiation protection, it can be seen that the collective annual doses of the nuclear medicine clinics in Brazil are on the whole higher than those of the CNAAA workers.

This trend of higher collective annual doses in nuclear medicine clinics will increase over the next years.
